

Task Report

Task: 2

I was able to complete the task using BeautifulSoup Library. Firstly, I extracted the entire source code of the page. From the entire source code, I separated the part which was to be extracted according to the task. Then I used some basic logic and string manipulation to extract the required information and store it in a list of dictionaries. This list was then converted into Json and then stored in a file named "task_2.json".

BeautifulSoup is particularly good when it comes to handling small projects with low-level complexity. This is because it works with simple and flexible codes. And since I am new, I used BeautifulSoup for the task. Selenium is also great especially when we are dealing with a website that has a lot of features hinged on java. However, data size should be limited while using selenium.

Task: 1

I tried to attempt task 1 but could not complete it. I am an adaptive learner, and I am sure with the perfect guidance I will be able to pick things up in no time.
